(54) ROBOTIC VEHICLE FOR SOIL CULTIVATION

(57) The invention relates to a robotic vehicle (100) for movable operation in a work area (108), the movable operation comprising a soil cultivation, the work area (108) being represented by a set of discretized coordinate grid points (112), the vehicle (100) comprising a position detector and a controller (118), the controller (118) comprising a memory (122) and a processor, the memory (122) comprising instructions (124), wherein execution of the instructions (124) by the processor causes the vehicle (100) for performing a quality determination process comprising for a given grid point and a first point in time determining a quality with which the vehicle can be navigated at the given grid point using the position detector, wherein execution of the instructions (124) by the processor further causes the vehicle (100) to

- perform an initialization process, the initialization process comprising repeatedly performing the quality determination process at different first points in time and different given grid points selected from a subset of the grid points (112),
- abort the initialization process in case the number of grid points for which the quality with which the vehicle can be navigated at the given grid point was determined exceeds a predefined initialization threshold.

Description

[0001] The invention relates to a robotic vehicle for soil cultivation, a method for operating a robotic vehicle and a computer program product.

[0002] State-of-the-art robotic vehicles are known for soil cultivation. For use in areas with different soil conditions or obstacles on the surface to be machined a precise determination of position of the robot vehicle is necessary. For example, WO2017092798 A1 relates to a robotic work tool for movable operation within a work area. The robotic lawnmower comprises a satellite navigation device; and a controller, the controller being configured to cause the robotic work tool to movably operate within the work area based on positions partly or in whole determined from satellite signals received by the satellite navigation device being a differential satellite navigation device and on phase information received from a reference station.

[0003] It is an objective to provide for an improved robotic vehicle for soil cultivation, an improved method for operating a robotic vehicle and a computer program product.

[0004] Disclosed is a robotic vehicle for movable operation in a work area, the movable operation comprising a soil cultivation, the work area being represented by a set of discretized coordinate grid points. The vehicle comprises a position detector. The position detector can be an optical detector like a camera, it can be a detector that determines the vehicle's position using external guiding beacons, it could be a radar system that detects the vehicle's position using radar detectable known reference points etc. In one embodiment the position detector is or comprises a Global Navigation Satellite System, GNSS, receiver. Generally, each grid point represents a respective area segment, i.e. tile, of the work area.

[0005] The vehicle further comprises a controller, the controller comprising a memory and a processor, the memory comprising instructions, wherein execution of the instructions by the processor causes the vehicle for performing a quality determination process comprising for a given grid point and a first point in time determining a quality with which the vehicle can be navigated at the given grid point using the position detector.

[0006] The quality with which the vehicle can be navigated at the given grid point using the position detector may for example the accuracy, at which the real location of the vehicle at the given grid point can be determined. For example, in case of various guiding beacons the accuracy may vary depending on the number of beacons receivable at the vehicle. In case of a GNSS receiver, the accuracy may vary depending on the number of satellites visible at the vehicle. In case of an optical detector the accuracy may vary depending on the visibility conditions and the recognition value of the present environment of the vehicle.

[0007] The execution of the instructions by the processor further causes the vehicle to perform an initialization

process, the initialization process comprising repeatedly performing the quality determination process at different first points in time and different given grid points selected from a subset of the grid points. The execution of the instructions by the processor further causes the vehicle to abort the initialization process in case the number of grid points for which the quality with which the vehicle can be navigated was determined exceeds a pre-defined initialization threshold.

[0008] In case the position detector is comprising a Global Navigation Satellite System, GNSS, receiver, the quality determination process is comprising an or being given by an accuracy determination process comprising for the given grid point and the first point in time receiving a first set of GNSS signals from a vehicle base, e.g. a mower base being spaced apart from the vehicle, the first set of GNSS signals having been acquired by the vehicle base at the first point in time, the vehicle base being spaced apart from the vehicle, receiving at the first point in time a second set of GNSS signals from the GNSS receiver, . Here, the determining of the quality with which the vehicle can be navigated at the given grid is comprising or is given by an accuracy of a e.g. hypothetical or real location determination, the location determination being based on the second set of GNSS signals, the determination of the accuracy being based on a comparison of the signal qualities of the first set of GNSS signals and the second set of GNSS signals.

[0009] Unless otherwise mentioned, without restriction to generality in the following it is assumed that the position detector is a GNSS receiver and that GNSS signals are used for a location determination.

[0010] A robotic vehicle may be any self-propelled vehicle that autonomously moves within the work area. For example, the vehicle is battery-powered and makes use of the vehicle base the vehicle is able to automatically travel to in order to be recharged.

[0011] A navigation of a vehicle is understood as a guiding of the vehicle to a desired grid point using the vehicle's position detector to determine the vehicle's real position relative to the desired grid point.

[0012] The soil cultivation may comprise mowing of a lawn, core aerification (recommended practice for many lawns reducing soil compaction and thatch, improve surface drainage etc.), watering of soil areas etc. For example, the robotic vehicle is a robotic lawn mower.

[0013] The "vehicle base" is understood as a fixed base comprising a GNSS receiver for receiving the first set of GNSS signals. The purpose of the vehicle base may be manifold. For example, the base could serve as a shelter for the robot to protect it from the weather when the robot is not in use. The base could serve as a charging station for the robot. Or the base could serve as a reference position for the robot, in which case the exact position of the base should preferably be known. In this case a later exact position determination of the robot via differential GNSS (especially differential GPS) is possible. Differential Global Positioning Systems (DGPS) are

e.g. enhancements to the Global Positioning System (GPS) which provide improved location accuracy, in the range of operations of each system. A fixed ground-based reference station may be used to broadcast the difference between the positions indicated by the GPS satellite system and its known fixed position. Receiver stations may correct their positions based on that difference.

[0014] GNSS signals may be signals originating from satellites of the GPS, GLONASS, Galileo or BeiDou system. The GNSS positioning for obtaining a receiver's position is derived through various calculation steps. In essence, a GNSS receiver measures the transmitting time of GNSS signals emitted from four or more GNSS satellites and these measurements are then used to obtain its position (i.e., spatial coordinates) and reception time.

[0015] It has to be noted that that location determination does not have to be performed in such a manner that a real spatial position is obtained from that. It may be sufficient to calculate the uncertainty that may exist in case a determination of the spatial position using the position detector, e.g. from the second set of GNSS signals would be performed. Typically, trilateration is used for GNSS based spatial position determination, wherein for the above described accuracy determination it may be sufficient to know "size" of the zone of uncertainty the spheres in trilateration will intersect.

[0016] In order to permit the robotic vehicle to determine at which grid point it is actually located, either the second set of GNSS signals may be used for that purpose or other means may be used that permits to determine the actual location of the vehicle. For example, any kinds of optical systems, acoustical systems and beacon guidance systems may be used for that purpose. Further, if available, a deduced reckoning navigation device of the vehicle may be used for that purpose.

[0017] Embodiments may have the advantage, that the accuracy of a location determination is available at rather high accuracy. The accuracy of position detection data, e.g. GNSS data may depend on many factors. In case of GNSS signals, one source of errors in the GNSS position accuracy originate from multipath effects. Multipath occurs when part of the signal from the satellite reaches the receiver after one or more reflections from the ground, a building, or another object. First at all, these reflected signals can interfere with the signal that reaches the receiver directly from the satellite. Second, due to the range delay in multipath due to the result of the reflection of the GNSS signal the position as determined using such a multipath signal is falsified. Another source of errors are weak signals. Signals from other high-frequency transmitters can interfere with the GNSS receiver even at low field strengths, resulting in measurement errors and interference from high-frequency signals. Potential sources of interference may for example include harmonics of the transmission frequencies of TV and radio transmitters, mobile telecommunication system networks and radar transmitters.

[0018] By comparing the signal qualities of the first set of GNSS signals and the second set of GNSS signals the (hypothetical) accuracy of a location determination based on the second set of GNSS signals is not solely relying on this second set of GNSS signals but also considers the first set of GNSS signals. The signal qualities like signal-to-noise ratios or signal intensities of the first and second set of GNSS signals may permit to identify and omit parts of the second set of GNSS signals that are of low quality, i.e. that may be multipath signals, signals disturbed by interference with other non-GNSS-based signals etc.

[0019] In one example, an obstacle may shadow GNSS reception partially at a certain grid point and point in time. In case the accuracy of location determination would solely be based on the second set of GNSS signals, such a grid point may erroneously be evaluated as a good grid point which position is reliably determinable using GNSS signals, even though the respective position determination would be rather imprecise due to multipath errors and interferences. By additionally considering the first set of GNSS signals that was recorded at that point in time, e.g. multipath errors can be easily detected due to the spatial distance of the vehicle base GNSS receiver from the vehicle GNSS receiver and most probably the absence of similar GNSS signal reflections at the vehicle base and the GNSS receiver.

[0020] Embodiments may further have the benefit that the information necessary to start the movable operation with high quality localization and a decent coverage of the work area is quickly available. Instead of collecting unnecessary data for later performing the moveable operation, the initialization phase is terminated when the initialization threshold value is reached.

[0021] In accordance with an embodiment, the predefined initialization threshold is a minimum share of grid points relative to all grid points of the set of discretized coordinate grid points. For example, the minimum share is in between 60% and 80%, preferably 65% or 70% or 75%.

[0022] In accordance with an embodiment, execution of the instructions by the processor further causes the vehicle for planning the movable operation based on at least some of the grid points for which a quality with which the vehicle can be navigated, e.g. an accuracy of the location determination is available and the quality with which the vehicle can be navigated, e.g. the accuracy of the location determination.

[0023] This may have the benefit that navigation of the vehicle for performing the movable operation like e.g. mowing a lawn can be performed at a rather high precision since only grid points are considered here for which it can be made sure that a quality with which the vehicle can be navigated, e.g. an accuracy of the location determination is available. For example, by considering the accuracy of the location determination only such grid points may be traveled during the movable operation for which a certain minimum quality of navigation precise-

ness can be met.

[0024] In accordance with an embodiment of the invention the first and second GNSS signals are received from satellites that are located at certain satellite positions in the sky above the base and the vehicle, the comparison of the signal qualities of the first set of GNSS signals and the second set of GNSS signals resulting in a quality number per satellite position. This may permit to have a basis for evaluating the quality of a certain satellite position for e.g. usage of the respective satellite GNSS signals for the accuracy determination of the location determination.

[0025] In accordance with an embodiment, execution of the instructions by the processor causes the vehicle further for performing a predicting process for at least some of the grid points, the predicting process forecasting the accuracy of a location determination for points in time future to the respective first point in time. This may be beneficial in case during the initialization process some of the coordinate grid points of the work area where missed or not covered. By means of the predicting process it may be possible to obtain a contiguous area on which the vehicle can operate.

[0026] In accordance with an embodiment, the predicting process forecasting the accuracy of the location determination for at least some of the grid points of the subset is using at least one of GNSS Ephemerides, Almanacs and satellite repeat cycles applied on the first or second set of GNSS signals received at the respective first point in time. Broadcast ephemerides are forecasted, predicted or extrapolated satellite orbits data which are transmitted from the satellite to the receiver in the GNSS signal. Alternatively or additionally daily GNSS broadcast ephemeris files may be used which are may be downloaded e.g. via a wide area network and which a merge of the individual GNSS data files into one file. Compared to GNSS ephemerides, the GNSS almanacs contains less accurate orbital information than ephemerides, however with longer validity. The repeat cycle of a describes the fact that a satellite generally follows an elliptical path around the Earth. The time taken to complete one revolution of the orbit is called the orbital period. The satellite traces out a path on the earth surface, called its ground track, as it moves across the sky. As the Earth below is rotating, the satellite traces out a different path on the ground in each subsequent cycle. The time interval in which nadir point of the satellite passes over the same point on the Earth's surface for a second time (when the satellite retraces its path) is called the repeat cycle of the satellite.

[0027] Any of these GNSS Ephemerides, Almanacs and satellite repeat cycles may be used to predict at which point in time in the future a satellite constellation may be available again that in a certain manner reflects the satellite constellation for the given grid point that was given during the initialization phase. This may permit a reliable and easy future planning of future movable operation of the vehicle. Simply spoken, in case for certain

satellite constellation at a certain the grid points and time the accuracy of location determination that was considered as being a good, this fact can be used at the future point in time thus also knowing in that in that future point in time the quality of position determination of the vehicle will be also good.

[0028] In accordance with an embodiment, the predicting process forecasting the accuracy of the location determination is comprising: forecasting a reception of first or second GNSS signals for said points in time future to the first point in time from satellites located at a sky area around the certain satellite positions, the accuracy of the location determination being forecasted using the forecasted reception of the first or second GNSS signals.

[0029] This may have the benefit that only GNSS signals originating from satellites and is sky area in close vicinity to the certain satellite positions are used for forecasting the reception of the first and second GNSS signals for a future point in time. As mentioned above, this may permit a reliable and easy future planning of future movable operation of the vehicle.

[0030] For example, per satellite position the forecasting of the accuracy of the location determination is performed using either the forecasted reception of the first GNSS signals weighted by the quality number of that satellite position or the forecasted reception of the second GNSS signals excluding GNSS signals from satellite positions for which the quality number does not fulfill a first minimum quality criterion.

[0031] Here, the first alternative realizes that certain first GNSS signals may be blocked at the grid point due to obstacles. Blocking may be only partially or completely, which however has certain negative effect on the quality of position determination. The weighting of a first GNSS signal received from certain satellite position with the quality number of that satellite position therefore accounts for that possibility that in the end that satellite position may be partially or fully shadowed and therefore not be fully available for a high-quality location determination. The quality number may for example be a ratio between the second GNSS signal and the first GNSS signal intensities or S/N-ratios. Any other means that reflect the quality of a received signal may also be employed here.

[0032] In the second alternative only the second GNSS signals are used, however with the limitation that GNSS signals are excluded in case the quality number does not fulfill certain first minimum quality criterion. This may have the benefit that satellite signals are excluded from any forecasting of signal receptions from which it is known that they may negatively influence the location determination procedure.

[0033] In accordance with an embodiment, the sky above the base and the vehicle is represented by a set of discretized zones, the sky area around a certain satellite position being confined by the boundaries which confine the zone in which the satellite position is located. For example, the sky above the GNSS receiver of the

vehicle may be projected onto a 2D matrix represented by a coordinate grid, the coordinate grid forming individual zones. A skyplot provides the possibility to represent satellite positions within such a 2D matrix in a polar projection. The position of the satellite inside the outer circle of such a skyplot indicates the two angles azimuth and elevation. The azimuth may be drawn as central angle and the elevation may be provided as circle radius. Different elevations may correspond to individual grid circles of respectively different diameters. The individual azimuth angles may be represented as lines originating from the center of the skyplot towards the outer circle. These lines therefore also correspond to parts of the coordinate grid. In total, the coordinate grid is made up of the circles and the lines.

[0034] By using a skyplot it is not necessary to just rely on a single exact satellite position in the sky but to account for the fact that certain variation of the given satellite position in the sky around that satellite position will not significantly affect the total quality of location determination in case the reception conditions of signals from this satellite position was considered as being good or sufficient enough.

[0035] In accordance with an embodiment of the invention, the predicting process is further comprising determining a sky area of good reception which comprises at least some of the certain satellite positions for which the quality number of that satellite position fulfills a first minimum quality criterion, the sky area around a certain satellite position being confined by the boundaries which confine the sky area of good reception. This may be beneficial in case the higher number of satellites are available for which the quality of signal reception is rather good. In case the satellites are evenly distributed over the sky, certain shadow areas may be easily identifiable. In the case from the satellite positions for which the quality number fulfills the first minimum quality criterion it is possible to draw as a contour line regarding the shadowed area, any position the of the sky outside the shadow area can be considered as the area of good reception. As a consequence, it may again not be necessary to just rely on a single exact satellite position in the sky but to account for the fact that a variation of location of the satellite positions within the area of good reception in the sky will not significantly (if at all) affect the total quality of location determination.

[0036] In accordance with an embodiment, the determination of the accuracy of the location determination is only considering GNSS signals from satellite positions for which the quality number of that satellite positions fulfills a first minimum quality criterion. This principle may be applied as a general rule within the whole described process as it may ensure that the determination of the accuracy of the location determination is only performed with the respect to signals that meet a certain quality. It has to be noted that the quality number may comprise, as described above, a ratio between the second GNSS signal and the first GNSS signal intensities or S/N-ratios.

[0037] The quality number may also rate the position of the individual satellites in the sky. For that purpose, a weighting of the quality number by the Dilution of precision (DOP) may be used such that for certain unfavorable satellite constellations the respective quality numbers may be automatically negatively influenced. Generally, the relative satellite-receiver geometry plays a major role in determining the precision of estimated positions. When visible navigation satellites are close together in the sky, the geometry is said to be weak and the DOP value is high; when far apart, the geometry is strong and the DOP value is low. Thus, a low DOP value represents a better positional precision due to the wider angular separation between the satellites used to calculate the vehicle's position.

[0038] In accordance with an embodiment, in case with respect to a given grid point the quality number for a certain satellite position does not fulfill a first minimum quality criterion, for that grid point any GNSS signals from said satellite position are excluded for the planning of the movable operation. In case for example the vehicle is crossing a given grid point multiple times and it occurs once that a GNSS signals from a certain satellite position does not fulfill the first minimum quality criterion, for the planning of the movable operation GNSS signals originating from that certain satellite position will always be excluded, irrespective if later on the quality of GNSS signals originating from that certain satellite position may improve. This may have the benefit that for all times a rather robust approach is provided based on which a precise navigation of the vehicle is possible using as trajectory at least part of the grid points for which then accuracy of the location determination is available and the accuracy of the location determination is sufficiently high. For example, a large vehicle like for example a caravan may obstruct at a given grid point some GNSS signals from certain satellite positions. Irrespective if the caravan is present or not, the approach is based on the worst-case scenario in which the caravan is present regarding the planning of the movable operation. Thus, it may be ensured that soil cultivation will be possible at high positioning precision, irrespective if the caravan is there or not.

[0039] This principle of exclusion of satellite positions holds true for both, the initialization phase in which state of for the same grid points may be recorded multiple times as different points in time, as well as for the actual soil cultivation process, i.e. the movable operation during which a grid point used in the initialization phase or later may also be crossed once or multiple times.

[0040] In accordance with an embodiment, the predicting process is comprising an interpolation, the interpolation being performed for at least some of the grid points for which the quality with which the vehicle can be navigated, e.g. the accuracy of a location determination for points in time future to the respective first point in time is yet unavailable, the interpolation considering grid points e.g. directly adjacent to each other for which the quality

with which the vehicle can be navigated, e.g. the accuracy of a location determination for points in time future to the respective first point in time is available, the interpolation resulting in estimated accuracies of location determination for the grid points for which the interpolation was performed.

[0041] This may have the benefit that it is not necessary to have an initialization phase that covers all grid points of the work area and which consequently it would take significant amount of time for e.g. GNSS acquisition. Instead, the interpolation is performed which assumes that for example for neighboring grid points the variation in location determination accuracy will only vary by small amounts. The interpolation may further consider the course of the location determination accuracy between different grid points, such that with a rather high precision an estimation can be made regarding the location determination accuracy for neighboring grid points.

[0042] For example, the interpolation is performed during the initialization process. This may have the benefit that already during the initialization process for additional grid points the accuracy of the location determination is available, such that the abortion of the initialization process can also take the interpolated grid points into account. This may significantly shorten the initialization process.

[0043] In accordance with an embodiment, during the initialization process the vehicle is randomly moving within the work area, the random movement directing the vehicle to the grid points of the subset of the grid points. For example, the grid points of the subset may result from the random movement of the vehicle. Vice versa it is also possible that the grid points of the subset are randomly selected and that the vehicle is then directed randomly to these grid points. Generally, this may have the benefit that the individual grid points are more or less evenly distributed over the work area such that each for example the above-mentioned interpolation is effectively available for being performed for a large number of grid points. A further benefit may be that due to the random distribution of the grid points when aborting the initialization process it is highly probable that the accuracy of a location determination is available for a more or less equally distributed subset of the grid points. This would be helpful for providing a good coverage of the work area with accuracies of location determination being directly available via the received GNSS data or indirectly available via interpolation for the major part of the work area.

[0044] In accordance with an embodiment, the planning of the movable operation comprises clustering of at least some of the grid points for which the quality with which the vehicle can be navigated, e.g. the accuracy of the location determination is available, the clustering resulting in one or more sets of clustered grid points, wherein for each set of the clustered grid points starting from a respective second point in time moving of the vehicle along said set of clustered grid points guided using the position detector and respective signals therefrom, e.g.

a third set of GNSS signals received from the GNSS receiver during said movement is possible with an accuracy of the location determination during the guiding fulfilling a second minimum quality criterion. Preferably, for a given one of the sets each of the grid points have at least one immediately adjacent grid point in that set.

[0045] The clustering may have the benefit that a basis is provided on which a scheduling of the moveable operation is possible in an easy manner. Generally, the clustering ensures that starting from a certain time in future the vehicle is able to navigate along grid points of a set of clustered grid points in such a manner, that the quality of navigation is sufficiently high, i.e. that a precise navigation in terms of location determination is guaranteed.

[0046] In accordance with an embodiment, the work area is comprising boundaries confining the work area, wherein for grid points lying within a predefined boundary zone bordering the boundaries the second minimum quality criterion is tightened up, for example by a relative value, for example a value in between 10% and 30%. This may have the benefit that an unintentional movement of the vehicle out of the work area is prohibited due to an imprecise location determination at the boundaries of the work area. The predefined boundary zone may be an edge strip with a given width, which borders with a side directly to the boundaries.

[0047] In accordance with an embodiment, at least one of the predicting process and the clustering are comprising for a grid point: adjusting the associated accuracy of location determination taking into account that the position determination is additionally performed using a deduced reckoning position estimate obtained from a deduced reckoning navigation device of the vehicle. For example, the taking into account that the position determination is additionally performed using the deduced reckoning position estimate is restricted to grid points located within a maximum predefined distance from a grid point for which the unadjusted associated accuracy of location determination fulfills the second minimum quality criterion.

[0048] This is based on the insight that even without a high-quality GNSS location determination being available, starting from a precisely known location and using additionally that deduced reckoning position estimate it is still possible to supplement the GNSS location determination with additional deduced reckoning position data standing for example from odometry, such that in total the accuracy of location determination is sufficiently high for performing the movable operation.

[0049] Since the usage of the deduced reckoning position estimate is restricted to grid points located within a maximum predefined distance from a grid point, it may be ensured that location determination errors occurring when using the deduced reckoning position estimate are not accumulating in a manner that the total accuracy of location determination would be influenced in a negative manner.

[0050] A "deduced reckoning navigation device" may

comprise anyone of a direction component that can receive x-axis and y-axis acceleration information from sensors, e.g., gyroscopes and accelerometers, gravitational sensors. Further, it may comprise compresses, odometric sensors etc. Odometric sensors are generally motion sensors which provide motion information for usage in odometry, i.e. an information about a change in position over time. Odometry makes for examples usage of the knowledge about the vehicles driving wheel circumference and recorded wheel rotations and steering direction in order to calculating the vehicle's current position by using a previously determined (reference) position. Generally, a deduced reckoning navigation device in the context of the present disclosure is a device that besides GNSS signal information uses any available sensor information for dead reckoning. In navigation, dead reckoning is the process of calculating one's current position by using a previously determined position, or fix, and advancing that position based upon known or estimated speeds over elapsed time and course.

[0051] In accordance with an embodiment, the planning of the movable operation is comprising scheduling the movable operation for obtaining a movement trajectory of the vehicle for performing the movable operation, the scheduling comprising selecting one or more of the sets of clustered grid points, the movement trajectory comprising the grid points of the one or more sets of clustered grid points. This may have the benefit that either starting from the desired point in time for example set by a user the actual movable operation is performed, or that the scheduling itself is selecting at most suitable starting point in time based on the clustered grid points starting from which the movable operation can be performed in e.g. a rather efficient manner. For example, an efficient manner would be a manner in which in a consecutive way the majority of clusters grid points can be covered by the movement trajectory.

[0052] In accordance with an embodiment, execution of the instructions by the processor further causes the vehicle for performing a movement of the vehicle to said selected one or more of the sets of clustered grid points and repeating the steps of the accuracy determination process during the movement for the grid points traveled during the movement and with the first point in time being the actual point in time of movement on the respective grid point. As a consequence, the available data regarding location determination accuracy is more and more completed with real measurements data of GNSS signals for different points in time. For example, the movement of the vehicle may also in walls movement over grid points for which only interpolation accuracy data is available. This interpolation accuracy data can then be completed by real measurement data based on GNSS signals. That repetition of the steps of the accuracy determination process may also involve further interpolation, predicting and taking into account that the deduced reckoning position estimate may be used.

[0053] In accordance with an embodiment, the move-

ment trajectory obtained for a single contiguous movable operation results in a fragmentation degree of the work area, the fragmentation degree describing the degree of fragmentation of the work area with respect to subareas of the area covered by the trajectory, wherein in case the fragmentation degree is above a predefined fragmentation threshold, the second minimum quality criterion is successively relaxed within specified limits until the degree of fragmentation is below the predefined fragmentation threshold. Fragmentation is understood as follows: if the subareas of the area covered by the trajectory are not continuously and without gaps covered by the trajectory, but there are "pieces of uncovered subareas (fragments) between them, this is understood as a fragmentation.

[0054] This may have the benefit that in contiguous manner at rather large part of the work area can be processed by means of the movable operation in a quick manner. Instead of having the vehicle performing the movable operation on the individual sets of clustered grid points each separated by respective unprocessed gaps of the work area, the movable operation may therefore be performed in quicker none interrupted manner. It has to be noted here that each interruption of the movable operation will require, that the vehicle has to perform additional movements in order to compensate for this interruption.

[0055] In accordance with an embodiment, the vehicle is further comprising a compass, wherein execution of the instructions by the processor further causes the vehicle for performing the planned movable operation resulting in a movement of the vehicle, wherein in case moving of the vehicle guided using the position detector and respective position signals therefrom, e.g. GNSS signals received from the GNSS receiver during said movement is not possible any more with an accuracy of the location determination during the guiding fulfilling a fourth minimum quality criterion: determining the heading of the vehicle using the compass, determining the compass direction in which the area lies, in which the vehicle was last guided with the quality with which the vehicle can be navigated, e.g. the accuracy of the location determination during the guiding fulfilling the second minimum quality criterion. This may be considered as for example a backup solution in a case for whatever reason the vehicle gets displaced in an unforeseen manner from the position in which the vehicle was last guided. For example, the vehicle may get offset by being hit by person or an animal or the vehicle may start to slip into a certain direction on a step hill. With the fourth minimum quality criterion having a requirement on quality lower than the second minimum quality criterion, the vehicle may not be able to determine its actual location in the precise manner. Nevertheless, by using the heading of the vehicle using its compass and the compass direction in which the area lies in which the vehicle was last guided with the accuracy of the location determination during the guiding fulfilling the second minimum quality criterion, it is possible to turn the vehicle and move it towards the

area using a compass based navigation approach.

[0056] In accordance with an embodiment, the abortion of the initialization process is performed in case the number of grid points for which the quality with which the vehicle can be navigated, e.g. the accuracy of the location determination was determined to fulfill a (the) second minimum quality criterion exceeds the predefined initialization threshold. This may be beneficial in that when later performing the movable operation the vehicle localization during the guidance of the vehicle is guaranteed to be performed with high accuracy. Scenarios are avoided in which the initialization phase was aborted but the number of grid points that are really useful for a precise guiding (i.e. that have associated an accuracy of the location determination fulfilling the second minimum quality criterion) is too low in order to have decent coverage of performing the movable operation on the work area.

[0057] In accordance with an embodiment, the work area is comprising boundaries confining the work area (this was already mentioned above), wherein for critical grid points lying within a predefined boundary zone bordering the boundaries and for which no quality with which the vehicle can be navigated, e.g. no accuracy of a location determination is available or for which the accuracy of a location determination does not fulfill the second minimum quality criterion, the scheduling further comprises sending a signal to a user in case the movement trajectory of the vehicle is within a predefined distance from the critical grid points.

[0058] The boundaries confining the work area were already mentioned above. The predefined boundary zone was also mentioned above. The second minimum quality criterion may eventually be tightened up for this embodiment, similar as already described above with respect to the boundary zone.

[0059] This may have the advantage that the user is informed about the possibility to e.g. manually direct the vehicle towards the critical grid points for performing the accuracy determination for these grid points in case the mower is close to these critical grid points during its regular movable operation. Thus, this manual "training" of the vehicle for performing the accuracy determination for the critical grid points may be done in a time efficient manner because the vehicle will then already be close (within the predefined distance) to these critical grid points when following the movement trajectory.

[0060] In accordance with an embodiment, the signal is indicating the one or more points in time when the movement trajectory of the vehicle is within the predefined distance from the critical grid points. This may permit the user in a user friendly-manner to prepare himself/herself in due time for being ready for performing e.g. a manual guidance of the vehicle towards the critical grid points.

[0061] In accordance with an embodiment, execution of the instructions by the processor further causes the vehicle for receiving remote-control signals from the user in response to the sending of the signal to the user, the

remote-control signals causing the vehicle for performing a movement of the vehicle to one or more of the critical grid points and repeating the steps of the accuracy determination process during the movement for either only the critical grid points or all the grid points traveled during the movement and with the first point in time being the actual point in time of movement on the respective grid point.

[0062] In another aspect, the invention relates to a method for operating a robotic vehicle for movable operation in a work area, the movable operation comprising a soil cultivation, the work area being represented by a set of discretized coordinate grid points, the vehicle comprising a position detector, the method comprising performing a quality determination process comprising for a given grid point and a first point in time determining a quality with which the vehicle can be navigated at the given grid point using the position detector, wherein the method further comprises performing an initialization process, the initialization process comprising repeatedly performing the quality determination process at different first points in time and different given grid points selected from a subset of the grid points; aborting the initialization process in case the number of grid points for which the quality with which the vehicle can be navigated was determined exceeds a predefined initialization threshold.

[0063] This method may for example be a computer implemented or it may be realized by an Application-Specific Integrated Circuit (ASIC).

[0064] In another aspect, the invention relates to a computer program product comprising computer executable instructions to perform the method as described above.

[0065] The above described examples and embodiments may be combined freely as long as the combinations are not mutually exclusive. It further has to be noted that in case above it is understood that any mentioned first minimum quality criterion is always the same first minimum quality criterion, any mentioned second minimum quality criterion is always the same second minimum quality criterion.

[0066] In the following, embodiments of the invention are described in greater detail in which

Figure 1 shows robotic vehicle performing an initialization process in a work area,

Figure 2 illustrates an exemplary skyplot as seen from the vehicle,

Figure 3 shows different combined skyplots at different points in time for the given grid point,

Figure 4 shows a first set of clustered grid points with respect to a given starting time point,

Figure 5 shows a second set of clustered grid points with respect to another a given starting time point,

Figure 6 is schematic of robotic vehicle,

Figure 7 is a flowchart of method for operating a robotic vehicle,

Figure 8 is a flowchart illustrating a clustering proc-

ess.

[0067] In the following similar features are denoted by the same reference numerals. Without restriction to generality in the following it is assumed that the robotic vehicle is a lawnmower and that the soil cultivation is the mowing of the lawn of a work area. Further, it is assumed that the position detector comprises a GNSS receiver and that the position detection is based on GNSS signals. Figure 1 illustrates a lawnmower 100 located within a work area 108 to be processed.

[0068] The work area 108 is represented by a set of discretized coordinate grid points 112. As a result, the work area 108 is divided up into set of individual tiles 110.

[0069] The vehicle 100 is comprising a GNSS receiver 106 and a controller, which is illustrated in the inset of figure 1. The controller 118 comprises a processor 120 and a memory 122. That memory stores instructions 124, wherein execution of the instructions by the processor causes the vehicle for performing an initialization process and an accuracy determination process. Basically, the accuracy determination process comprises receiving for given grid point 112 at a certain time point a first set of GNSS signals from the vehicle base 104 which itself comprises a respective GNSS receiver 102. The base 104 is fixed and not movable, whereas the vehicle 100 can move over the lawn 108 to different grid points.

[0070] The accuracy determination process further comprises receiving a second set of GNSS signals 116 from the GNSS receiver 106. The first set of GNSS signals and the second set of GNSS signals were acquired at the same point in time by the respective GNSS receivers. The controller uses these two sets of GNSS signals using its instructions 124 to determine an accuracy of location determination based on a comparison of the signal qualities of the first and second set of GNSS signals 114 and 116, respectively. It will be understood that any further algorithms and computational approaches that will be discussed below are also performed by the controller using the instructions 124.

[0071] The initialization process is performed repeatedly at different points in time and for different ones of the grid points 112 and it comprises performing the above mentioned accuracy determination process. In other words, the accuracy determination process is performed for different ones of the grid points. For example, the mower is randomly moving over the work area 108 which results in subset of all grid points that represents the work area 108.

[0072] The initialization process is aborted in case a number of grid points for which the accuracy of the location determination was determined exceeds the predefined initialization threshold. For example, the initialization threshold may indicate a value of 80%, i.e. as soon as 80% of all grid points were subject to the determination of the accuracy of the location, the initialization process stops. Thereupon, based on the available grid points and the associated determined accuracy of location de-

termination the regular movable operation in the work area 108 can be started.

[0073] It has to be noted that it is possible that the soil cultivation process, e.g. the mowing of the lawn, can already performed during the initialization process. In case the mower will move randomly over the lawn during the initialization process, this will result in a randomly mowed lawn.

[0074] However, since the grid points that were traveled during the initialization process are well known, at a later point in time it is possible to additionally mow the remaining parts of the lawn that were not processed during the initialization phase. The clustering and/or scheduling which was discussed above may consider that.

[0075] Further showing in figure 1 is a user interface 132 which is in communicative connection with the controller 118. For example, the user interface 132 and the controller 118 may communicate over wireless communication means like while WLAN, Bluetooth, a telecommunications network, any wide area network, the Internet etc. the communication may involve sending of a signal 130 from the controller 118 to the user interface one of 132. The purpose of that will be described below in more detail.

[0076] As illustrated in figure 2, at a given grid point 112 the receiver 106 receives the GNSS signals 116 and 114 from different satellites 200 located at various satellite positions in the sky above the vehicle and the base. For some of the satellites 200 there may exist a direct line of sight between the GNSS receiver 106 and the respective satellite, whereas some GNSS signals may be blocked by obstacles, like for example the tree 500 as illustrated in figure 2. As a consequence, the signal qualities of the second set of GNSS signals 116 may vary from satellites to satellite.

[0077] The location of the satellite positions in the sky above the vehicle and the base may be represented using a skyplot 202, as illustrated in the inset of figure 2. The skyplot 202 is represented by a coordinate grid 204 and 205 forming individual zones 206. The position of the symbols 208 inside the outer circle 204 the skyplot indicate the satellites 200 at two angles azimuth and elevation. The azimuth is drawn as central angle and the elevation is provided as circle radius. Different elevations correspond to individual grid circles of respectively different diameters. The individual azimuth angles are represented as the lines 205 originating from the center of the skyplot towards the outer circle.

[0078] In the following it is assumed that the base has a full view of all satellites in the sky above a certain minimum elevation angle. Further it is assumed, that either the first set of GNSS signals 114 is uncorrected by the controller 118 when comparing the signal qualities of the first set of GNSS signals and the second set of GNSS signals. Uncorrected means here that the skyplots of the base and the mower are not adapted with respect to each other due to a different perspective the respective GNSS

receivers have on the same satellite constellations. This is because typically the mower 100 and the base 104 are located at rather short distances relative to each other in such a manner that the position of satellites within the respective skyplots only differ from each other within an irrelevant amount. The only requirement is that GNSS signals from different satellites as seen from the base and the mower can be associated with each other for performing the comparison of the signal qualities. However, in case the base 104 and the mower 100 are located at larger distances away from each other, the respective positions of the satellites 208 in the skyplots may be adjusted taking into account the different locations of the base and the mower.

[0079] With respect to the GNSS signals from a given satellite, these signals are compared with each other resulting in a quality number per satellite position. For example, the signal-to-noise ratios SN of the GNSS signals of a GNSS satellite at the base (SN1) and the mower (SN2) are used for that purpose. The quality number Q may then be given by the quotient $Q = SN2/SN1$. In case the quotient Q is close to 1, this corresponds to a good signal quality and in case the quotient Q is close to 0, this corresponds to a bad signal quality.

[0080] In a first step, for the given grid point any GNSS signals from satellite positions will be ignored for which the quality number Q does not fulfill a first quality criterion. For example, the first quality criterion may be that the signal quality needs to be higher than 0.8. In the below example the satellite located in the zone number 7 is excluded from any further accuracy calculations of the vehicle location because its quality number is below the quality criterion.

Zone 206	Quality Number Q
3	0.95
9	0.85
13	0.9
...	...

[0081] From all remaining satellite positions and the corresponding GNSS signals a practical or hypothetical accuracy of a location determination is calculated. This results in the following assignment of time point t of GNSS data acquisition, grid point GP and accuracy A:

t	GP	A
27.04.2017, 08:43:12	(12;56)	5cm
28.04.2017, 13:37:19	(12;56)	8cm
27.04.2017, 08:44:46	(12;59)	5cm
...	...	...

[0082] The content of the skyplot is illustrated in figure 3 for different points in time for a given grid point. The skyplots in figure 3 are skyplots, which already contain the combined information resulting from the comparison of the signal qualities of the first and second set of GNSS signals, i.e. they are based on the quality number Q. The reason for having the different skyplots in figure 3 is, that for example during the initialization phase the mower moved several times over the same given grid point, wherein each time a respective skyplot was recorded. This corresponds to for example the different time points as shown in the table above, 27.04.2017, 08:43:12 and 27.04.2017, 08:44:46. Another reason may be that during the actual mowing process the mower has also recorded the actually received second set of GNSS signals at the given grid point and is therefore able to generate additional skyplots from these signals.

[0083] In figure 3A, four satellite positions are illustrated, wherein one lower right zone of the skyplot contains a representation of satellite position 208 in a shaded manner. In the table above, this corresponds e.g. to the satellite in zone number 7 which due to its low quality number was excluded from any further accuracy calculations. As a consequence, for all times in future that respective zone number 7 will be ignored irrespective if later on the quality number may improve or not.

[0084] It has to be noted that one may define scenarios in which that exclusion of such a zone is reversed. One example may be that during later travels of the mower over the grid point the quality number for that zone fulfills n successive times the first quality criterion. The scenario may then be that in case $n > m$, m being a predefined number, the exclusion of the zone is reversed. In this case, the original measurement regarding the signal quality of that respective GNSS signal which led to the exclusion of the zone may be disregarded, while optionally any previous signal qualities that were determined for the zone may be considered for a respective recalculation of the accuracy of the location determination for previous points in time.

[0085] Figure 3B shows the skyplot 202 of the same grid points at second point in time. Compared to the skyplot of figure 3A, the skyplot is representing a further satellite position that also has quality number that does not fulfill the first quality criterion (shaded position on the top left). Consequently, this zone will also be excluded from any future accuracy determinations.

[0086] From figure 3A it becomes clear, that regarding the given point in time three satellites can be used for determining the accuracy of determination or calculation of the location of the mower at the given grid point. It has to be noted here that it is clear for the skilled person that in practice a position determination using only three satellites is not possible. Discussion is only for illustrative purposes and the skilled person will be able to extend the discussed principles to a number of satellites that is sufficient for performing a precise location determination.

[0087] Since in the figure 3B only two satellites are

available for the respective determination of an accuracy of location determination, this means that the accuracy for the time point at which the data for figure 3B was acquired is lower than the accuracy for the time point at which the data for figure 3A was acquired. Comparing figures 3A and 3B also illustrates that it is possible that the satellite positions may vary within the zones 206 slightly. The size of the zones may be adapted according to the needs of accuracy and the number of time points for which GNSS signal acquisition is available or desired.

[0088] In figure 3C, only the signals from two satellites are available, all having signal qualities that are fulfilling the first quality criterion.

[0089] Figure 3D shows a different approach. Here, the skyplot is divided into a blank area 302 and a shaded area 300. The shaded area 300 comprises one satellite position 208 for which the signal quality does not fulfill the first quality criterion. This shaded area 300 is flanked by a set of further satellite positions 208 for which the signal quality does fulfill the first quality criterion. In case a sufficient number of satellites is available which are arranged in a favorable constellation around a satellite position for which signal quality does not fulfill the first quality criterion, boundaries 304 may be calculated that delimit the blank area 302 as an "area of good reception" from the shadowed area 300. Instead of excluding a specific zone from any further accuracy calculations of the vehicle location because its quality number is below the quality criterion, the approach in figure 3D permits the possibility to exclude extended specific areas 300 from such calculations (or vice versa restrict the calculations to the specific area 302).

[0090] After having determined for different time points and grid points the respectively achievable accuracy of the location determination of the mower, it is now the goal to determine for future points in time when to start a mowing process. Since satellite constellations repeat periodically within satellite repeat cycles and since satellite constellations or satellite positions are predictable for future points in time using GNSS Ephemerides or Almanacs, it is possible to perform a predicting process for at least some of the grid points and for forecasting the accuracy of the location determination for points in time in future.

[0091] However, this only holds true for grid points for which already GNSS signals were acquired in the past. For grid points that are not yet covered by the mower, an interpolation may be performed. The interpolation is starting from grid points for which the accuracy of a location determination is already available, either from direct measurements or from the above-mentioned predictions.

[0092] As a result, for different points in time and grid points a dataset is obtained which comprises a mix of accuracy of location determinations, determined either from the direct measurements, predictions or interpolations.

[0093] From such a dataset, a clustering of grid points can be performed. For example, the clustering clusters

all grid points together in a suitable manner such that within the next 24 hours, 48 hours or any arbitrary time span the mower is able to process the lawn by means of mowing operation and a respective movement trajectory that covers these clustered grid points. The clustering may select a suitable starting time point for the mowing operation.

[0094] Figure 4 shows a first set of clustered grid points with respect to a given starting time point. Within the grid 108 the individual grid points are either marked with filled circles, empty circles or stars. Some of the grid points miss any markings. This is based on the assumption that when starting the mowing operation at a given time point and moving the mower along the trajectory 410, location determination is possible with sufficient high accuracy (accuracy of the location determination during the guiding fulfilling a second minimum quality criterion). The filled circles 400 represent grid points for which the accuracy of the possible location determination is available from satellite repeat cycle based prediction processes. The empty circles 404 represent grid points for which the accuracy of the possible location determination is available from broadcast Ephemeride calculations. The stars 402 represent grid points for which the accuracy of the possible location determination was determined by means of interpolation.

[0095] Further shown in figure 4 is an area of 408 which contains only one marked grid point. The reason is understandable from figure 5 which shows the area 108 is partially shadowed by an obstacle 500, a tree. In figure 4 the presence of the tree is illustrated by the contour line 406. The reason for the shadowing it is understandable from figure 5. Here, a satellite 200 is illustrated, wherein the obstacle 500 shadows the signals sent by the satellite 200 within shadow area of 502 of the work area 108. The finer the discretization of the work area with coordinate grid points, and the more data on achievable location accuracy is available in a clustering, the more precise will be the exact shape of the shadow area of 502. Since in figure 4 the grid is rough and the amount of data on achievable location accuracy within the area 408 is low, the trajectory 410 must completely omit area 408 since accurate GNSS based navigation is not possible within that area for the given time point of starting the mowing operation.

[0096] Figure 4 additionally shows within area 408 a shaded area of 420. Regarding area of 420 it is assumed that for grid points located in this area neither an accuracy of a location determination that did fulfill the second minimum quality criterion, nor an interpolation is available. The problem with area of 420 is, that a careless and too far driving into this area may cause the mower to leave the outer boundaries of the lawn 108. The grid points in this area are called critical grid points which are defined as grid points which lie within a predefined boundary zone bordering the boundary of a lawn and for which no accuracy of the location determination is yet available.

[0097] In order to nevertheless permit the mowing of

this area 420, the movement trajectory 410 which may be available for various different starting time points and which may vary from starting time point to starting time point is analyzed. The analysis is regarding the question whether the movement trajectory of the vehicle is within a predefined distance from the critical grid points. Regarding the critical grid points which fulfill this requirement the signal 130 (compare figure 1) is sent from the vehicle to the user interface 132. The signal indicates the respective points in time when the movement trajectory of the vehicle is within a predefined distance from the respective critical grid points which fulfill the above mentioned requirements.

[0098] The user may react on that by manually, carefully and remotely navigating the vehicle during said respective points in time towards the area 420. Being located on the respective grid points of the area of 420 the vehicle may perform the accuracy determination process for each respective critical grid point. A remote navigation may also be realized via the above mentioned wireless communication means. For that purpose, the user may for example use a computer or a Tablet PC or his smartphone which are each able to act as the user interface 132 and which may comprise a respective application for manually controlling a movement of the mower 100.

[0099] Regarding figure 5 it is assumed, that still within area of 408 a precise location determination of the mower is not possible. However, since for the grid points of the border line of area 408 additional data on achievable location accuracy is available. The respective trajectory 410 may be modified compared to figure 4 to also cover this area 408.

[0100] It has to be noted here that it even may be possible that the mower is moving into the area of 408 even though a GNSS based navigation it may not be a reliable enough anymore. For the grid points indicated by crosses in figure 5, a predicting process may be used that additionally takes into account that the position determination is additionally performed using a deduced reckoning position estimate. For example, when the mower is located at grid point 504, odometry may be used to move the mower to grid point 506. Just considering the second minimum quality criterion, in the predicting process the grid point 506 would have been excluded because the accuracy of the location determination does not fulfill a second minimum quality criterion. However, since a lower quality in location determination using GNSS could be improved using odometry, it is additionally considered if the accuracy of the location determination does fulfill the second minimum quality criterion. If this is the case, the associated accuracy of location determination is adjusted taking into account that the position determination is additionally performed using a deduced reckoning position estimate obtained from a deduced reckoning navigation device of the vehicle. This approach is only applied in case the respective grid point is located within a maximum predefined distance from a grid point for which the unadjusted associated accuracy of location determina-

tion fulfills the second minimum quality criterion. This minimizes the risk that due to accumulating errors arising from the deduced reckoning navigation the effective accuracy of location determination is decreasing so much that in practice the achieved accuracy is not acceptable any more, e.g. not fulfilling the second minimum quality criterion any more.

[0101] It further has to be noted that the above mentioned second minimum quality criterion may be tightened up for certain grid points that are defining the boundaries confining the work area 108. The reason is that under no circumstances the mower is allowed to leave the working area of 108. By tightening up the second minimum quality criterion, the location determination for these grid points at the boundaries can be performed with even higher accuracy thus minimizing the risk that due to navigational errors the mower is unintentionally leaving the area 108.

[0102] Figure 6 illustrates a schematic of a lawnmower 100 which comprises the GNSS receiver 106 and a further sensor 602 that may be used as a deduced reckoning navigation device. For example, the sensor 602 is a camera or a radar sensor which is able to acquire precisely a movement and/or location of the mower 100. The rotation of the wheels 600 may also be used for obtaining a deduced reckoning position estimate. The lawnmower 100 further comprises a rotating blade 604 for cutting grass and the controller 118. An engine 606 is powered by a battery 608, wherein the engine 606 is coupled to the wheels 604 moving the mower from the one grid points to the next grid point. The battery 608 may be recharged using the base which was discussed above with respect to figure 1.

[0103] Figure 7 is a flowchart of operating a robotic vehicle for movable operation in a work area. The method starts with step 700 with a certain grid point and the reception of the first set of GNSS signals from the vehicle base. In parallel in step 702, a second set of GNSS signals is received from the GNSS receiver of the vehicle. Thereupon, in step 704 a comparison is made of the signal qualities of the first and second set of GNSS signals and a quality number per satellite position is derived.

[0104] In step 705a check is made whether the number of available grid points for which the accuracy of the location determination was determined exceeds a predefined initialization threshold. If this is the case, a method continues with step 706. If it is not the case, then the method continues in step 705b with the movement of the vehicle to the next grid point and the repetition of steps 702 - 705a again.

[0105] Satellite positions which have a quality number that does not fulfill the predefined quality criterion are then excluded in this step 706. For the remaining satellites and the respective GNSS signals an accuracy of a location determination is then determined and stored together with the point in time of GNSS signal reception and grid point in a dataset.

[0106] Step 708 and 710 are optional: in step 708 a

sky area of good reception is determined which comprises at least some of the satellite positions for which the quality number of that satellite positions fulfills a respective minimum quality criterion. Thereupon, in step 710 for this area of good reception a forecasting of receiving GNSS signals from satellites located in this area of good reception is being made for forecasting an accuracy of a location determination for points in time future to the respective point in time when the signals were required in step 700 and 702. The forecasting is made for example using Ephemerides, Almanacs and satellite repeat cycles applied on the first or second set of GNSS signals received in steps 700 and 702. For this forecasting, a satellite is allowed to appear anywhere within the whole sky area of good reception. The forecasted accuracy of location determination is then stored together with the future point in time and grid point in the dataset.

[0107] In case steps 708 and 710 are not used, the method continues after step 706 with step 712 and the forecasting of an accuracy of a location determination for points in time future to the respective point in time when the signals were required in step 700 and 702. The forecasting is made for example using Ephemerides, Almanacs and satellite repeat cycles applied on the first or second set of GNSS signals received in steps 700 and 702. Compared to the forecasting that was made with respect to steps 708 and 710, this forecasting is based on the discrete satellite positions and sky areas around these satellite positions: in steps 700 and 702 the first and second GNSS signals were received from satellites that were located at certain satellite positions in the sky above the base and the vehicle. In step 712 a forecasting of a reception of first or second GNSS signals for future points in time from satellites located at a sky area around these certain satellite positions is made. From this forecasting, an accuracy of location determination is then determined and stored together with the future point in time and grid point in the dataset.

[0108] In optional step 714 an interpolation is being made for at least some of the grid points for which the accuracy of a location determination for certain points in time future to the respective point in time of reception is yet unavailable. I.e. for some points in time in the future, the accuracy of a location determination may already available and for some others not. In the latter case the interpolation may be used to complete the dataset regarding further future time points. The interpolation is considering grid points for which the accuracy of an already available location determination for future points in time is available. The interpolation is resulting in estimated accuracies of location determination for the grid points for which the interpolation was performed.

[0109] It has to be noted that the interpolation of step 714 may also be performed in between step 704 and step 705a. This would be beneficial in that additionally for performing the evaluation of step 705 interpolated data is available for various grid points, such that the criterion of a number of grid points for which the accuracy of the

location determination is available much quicker may exceed the predefined initialization threshold.

[0110] Step 716 comprises a clustering which will be described in more detail in figure 8. In essence, the clustering is resulting in one or more sets of clustered grid points, wherein for each set of the clustered grid points starting from a respective point in time moving of the vehicle along said set of clustered grid points guided using GNSS signals received the planning of the movable operation comprises clustering determination during the guiding fulfilling the second minimum quality criterion.

[0111] In step 718 the actual movable operation is performed which includes a planning of the operation. The planning comprises a scheduling of the movable operation for obtaining a movement trajectory of the mower for performing the movable operation, the scheduling comprising selecting one or more of the sets of clustered grid points, the movement trajectory comprising the grid points of the one or more sets of clustered grid points.

[0112] During the performance of the mowing operation, for each grid point traveled by the vehicle new GNSS signals may be received from the base and the vehicle receiver. All the signals may then be subject to the method steps 704-716 with the exception of steps 705a and 705b, which are repeated accordingly. The reason why steps 705a and 705b are not to be repeated here is, that these steps 705a and 705b are only necessary during the initialization process on the very beginning.

[0113] The more often steps 704-716 with the exception of steps 705a and 705b are repeated, the more precise the guidance of the vehicle can be even in the presence of shadows from full satellite reception because the dataset representing the grid points and associated accuracies of the location determination and time points is more and more filled such that even for critical grid points the clustering is able to find an appropriate point in time for which guidance of the vehicle is possible with the required accuracy.

[0114] Figure 8 is a flowchart illustrating a method of clustering of grid points. The method starts in step 800 with the clustering according to a second minimum quality criterion: the goal is that sets of clustered grid points are obtained that - starting from a certain future time point - can be traveled by the vehicle and for which (during this travel) a guidance of the vehicle using GNSS signals received during said traveling (movement) is possible with an accuracy of the location determination during the guiding fulfilling a certain (second) minimum quality criterion. In this manner, it is ensured that GNSS based guidance, eventually assisted by deduced reckoning position estimates, is possible at a decent positioning quality.

[0115] In optional step 802 it is checked if grid points are forming a boundary zone confining the work area. If this is the case, the method continues with step 804 in which the second minimum quality criterion is tightened up and the method jumps back to step 800 which then uses for the grid points of the boundary zone the tightened up (enforced) quality criterion. It has to be noted

here, that this procedure may also be reversed in that first all grid points forming the boundaries are identified and then for these identified grid points the quality criterion is tightened up. For the remaining grid points the quality criterion is set to the (non-tightened-up) second minimum quality criterion and thereupon the clustering process is performed. With this approach, a repetition may not be necessary.

[0116] In step 806 grid points are identified for which a deduced reckoning position guiding may be necessary. Generally spoken, these may be any grid points which do not yet fulfill the second minimum quality criterion. For the identified grid points, in step 808 it is checked whether the grid points are located within a maximum predefined distance from a grid point for which the unadjusted associated accuracy of location determination fulfills the second minimum quality criterion. In case the check is positive, for a grid point the associated accuracy of location determination is adjusted taking into account that the position determination is additionally performed using a deduced reckoning position estimate obtained from a deduced reckoning navigation device of the vehicle.

[0117] The method continues in step 812 which is a scheduling of the movable operation for obtaining a movement trajectory of the vehicle for performing the movable operation, the scheduling comprising selecting one or more of the sets of clustered grid points, the movement trajectory comprising the grid points of the one or more sets of clustered grid points. Each set of clustered grid points comprises respective time points and accuracies.

[0118] In step 814 it is additionally checked wherein the movement trajectory obtained for a single contiguous movable operation results in a fragmentation degree of the work area. The fragmentation degree is describing the degree of fragmentation of the work area with respect to subareas of the area covered by the trajectory. In case the fragmentation degree is above a predefined fragmentation threshold, the second minimum quality criterion is relaxed within specified limits in step 816 and the clustering process is repeated starting again from step 800. This repetition is performed with a more and more relaxing the second quality criterion until the degree of fragmentation is below the predefined fragmentation threshold.

[0119] Finally, in step 818 the movable operation is performed.

[0120] In summary, the invention may be described by the following clauses:

1. A robotic vehicle (100) for movable operation in a work area (108), the movable operation comprising a soil cultivation, the work area (108) being represented by a set of discretized coordinate grid points (112), the vehicle (100) comprising a position detector and a controller (118), the controller (118) comprising a memory (122) and a processor, the memory (122) comprising instructions (124), wherein execu-

tion of the instructions (124) by the processor causes the vehicle (100) for performing a quality determination process comprising for a given grid point and a first point in time determining a quality with which the vehicle can be navigated at the given grid point using the position detector, wherein execution of the instructions (124) by the processor further causes the vehicle (100) to

- perform an initialization process, the initialization process comprising repeatedly performing the quality determination process at different first points in time and different given grid points selected from a subset of the grid points (112),
- abort the initialization process in case the number of grid points for which the quality with which the vehicle can be navigated at the given grid point was determined exceeds a predefined initialization threshold.

2. The robotic vehicle (100) of clause 1, the position detector comprising a Global Navigation Satellite System, GNSS, receiver (106), the quality determination process comprising an accuracy determination process comprising for a given grid point and a first point in time:

- receiving a first set of GNSS signals (114) from a vehicle base (104), the first set of GNSS signals (114) having been acquired by the vehicle base at the first point in time, the vehicle base (104) being spaced apart from the vehicle (100),
- receiving at the first point in time a second set of GNSS signals (116) from the GNSS receiver (106), the determining of the quality with which the vehicle can be navigated at the given grid comprising a determining an accuracy of a location determination, the location determination being based on the second set of GNSS signals (116), the determination of the accuracy being based on a comparison of the signal qualities of the first set of GNSS signals (114) and the second set of GNSS signals (116).

3. The robotic vehicle (100) of clause 1 or 2, the predefined initialization threshold being a minimum share of grid points relative to all grid points of the set of discretized coordinate grid points (112).

4. The robotic vehicle (100) of any of the previous clauses, wherein execution of the instructions (124) by the processor further causes the vehicle (100) for planning the movable operation based on at least some of the grid points (112) for which a quality with which the vehicle can be navigated is available and the quality with which the vehicle can be navigated.

5. The robotic vehicle (100) of any of the previous

clauses, wherein the first and second GNSS signals are received from satellites (200) that are located at certain satellite positions (208) in the sky above the base (104) and the vehicle (100), the comparison of the signal qualities of the first set of GNSS signals (114) and the second set of GNSS signals (116) resulting in a quality number per satellite position (208).

6. The robotic vehicle (100) of any of the previous clauses, wherein execution of the instructions (124) by the processor causes the vehicle (100) further for performing a predicting process for at least some of the grid points (112), the predicting process forecasting the quality with which the vehicle can be navigated for points in time future to the respective first point in time.

7. The robotic vehicle (100) of clause 6, the predicting process forecasting the accuracy of the location determination for at least some of the grid points (112) of the subset using at least one of GNSS Ephemerides, Almanacs and satellite repeat cycles applied on the first (114) or second set of GNSS signals (116) received at the respective first point in time.

8. The robotic vehicle (100) of clause 6, the predicting process forecasting the accuracy of the location determination comprising: forecasting a reception of first or second GNSS signals for said points in time future to the first point in time from satellites (200) located at a sky area around the certain satellite positions (208), the accuracy of the location determination being forecasted using the forecasted reception of the first or second GNSS signals.

9. The robotic vehicle (100) of clause 8, wherein per satellite position (208) the forecasting of the accuracy of the location determination is performed using

- the forecasted reception of the first GNSS signals weighted by the quality number of that satellite position (208) or
- the forecasted reception of the second GNSS signals excluding GNSS signals from satellite positions (208) for which the quality number does not fulfill a first minimum quality criterion.

10. The robotic vehicle (100) of clauses 8 or 9, the sky above the base (104) and the vehicle (100) being represented by a set of discretized zones (206), the sky area around a certain satellite position (208) being confined by the boundaries which confine the zone (206) in which the satellite position (208) is located.

11. The robotic vehicle (100) of clause 8, the predicting process further comprising determining a sky

area of good reception (302) which comprises at least some of the certain satellite positions (208) for which the quality number of that satellite position fulfills a first minimum quality criterion, the sky area around a certain satellite position being confined by the boundaries which confine the sky area of good reception (302).

12. The robotic vehicle (100) of any of the previous clauses 5-11, wherein the determination of the accuracy of the location determination is only considering GNSS signals from satellite positions (208) for which the quality number of that satellite positions (208) fulfills a first minimum quality criterion.

13. The robotic vehicle (100) of clause 12, wherein in case with respect to a given grid point the quality number for a certain satellite position (208) does not fulfill a first minimum quality criterion, for that grid point any GNSS signals from said satellite position (208) are excluded for the planning of the movable operation.

14. The robotic vehicle (100) of any of the previous clauses 6-12, the predicting process comprising an interpolation, the interpolation being performed for at least some of the grid points (112) for which the quality with which the vehicle can be navigated for points in time future to the respective first point in time is unavailable, the interpolation considering grid points (112) for which the quality with which the vehicle can be navigated for points in time future to the respective first point in time is available, the interpolation resulting in estimated accuracies of location determination for the grid points (112) for which the interpolation was performed.

15. The robotic vehicle of clause 14, the interpolation being performed during the initialization process.

16. The robotic vehicle (100) of any of the previous clauses, wherein during the initialization process the vehicle (100) is randomly moving within the work area (108), the random movement directing the vehicle (100) to the grid points (112) of the subset of the grid points (112).

17. The robotic vehicle (100) of any of the previous clauses 4-16, wherein the planning of the movable operation comprises clustering of at least some of the grid points (112) for which the quality with which the vehicle can be navigated is available, the clustering resulting in one or more sets of clustered grid points (112), wherein for each set of the clustered grid points (112) starting from a respective second point in time moving of the vehicle (100) along said set of clustered grid points (112) guided using the position detector during said movement is possible

with an accuracy of the location determination during the guiding fulfilling a second minimum quality criterion.

18. The robotic vehicle (100) of clause 17, the work area (108) comprising boundaries confining the work area (108), wherein for grid points (112) lying within a predefined boundary zone bordering the boundaries the second minimum quality criterion is tightened up.

19. The robotic vehicle (100) of any of the previous clauses 2-18, at least one of the predicting process and the clustering comprising for a grid point (112) adjusting the associated accuracy of location determination taking into account that the position determination is additionally performed using a deduced reckoning position estimate obtained from a deduced reckoning navigation device (602) of the vehicle (100).

20. The robotic vehicle (100) of clause 19, wherein the taking into account that the position determination is additionally performed using the deduced reckoning position estimate is restricted to grid points (112) located within a maximum predefined distance from a grid point (112) for which the unadjusted associated accuracy of location determination fulfills the second minimum quality criterion.

21. The robotic vehicle (100) of any of the previous clauses 17-20, the planning of the movable operation comprising scheduling the movable operation for obtaining a movement trajectory (410) of the vehicle (100) for performing the movable operation, the scheduling comprising selecting one or more of the sets of clustered grid points (112), the movement trajectory (410) comprising the grid points (112) of the one or more sets of clustered grid points (112).

22. The robotic vehicle (100) of clause 21, wherein execution of the instructions (124) by the processor further causes the vehicle (100) for performing

- a movement of the vehicle (100) to said selected one or more of the sets of clustered grid points (112),
- repeating the steps of the accuracy determination process during the movement for the grid points (112) traveled during the movement and with the first point in time being the actual point in time of movement on the respective grid point (112).

23. The robotic vehicle (100) of clause 21 or 22, wherein the movement trajectory (410) obtained for a single contiguous movable operation results in a fragmentation degree of the work area (108), the

fragmentation degree describing the degree of fragmentation of the work area (108) with respect to sub-areas of the area covered by the trajectory (410), wherein in case the fragmentation degree is above a predefined fragmentation threshold, the second minimum quality criterion is successively relaxed within specified limits until the degree of fragmentation is below the predefined fragmentation threshold.

24. The robotic vehicle (100) of any of the previous clauses, further comprising a compass, wherein execution of the instructions (124) by the processor further causes the vehicle (100) for performing the planned movable operation resulting in a movement of the vehicle (100), wherein in case moving of the vehicle (100) guided using the position detector during said movement is not possible any more with an accuracy of the location determination during the guiding fulfilling a fourth minimum quality criterion,

- determining the heading of the vehicle (100) using the compass,
- determining the compass direction in which the area lies, in which the vehicle (100) was last guided with the quality with which the vehicle can be navigated during the guiding fulfilling the second minimum quality criterion.

25. The robotic vehicle (100) of any of the previous clauses, the abortion of the initialization process being performed in case the number of grid points for which the quality with which the vehicle can be navigated was determined to fulfill a second minimum quality criterion exceeds the predefined initialization threshold.

26. The robotic vehicle (100) of any of the previous clauses, the work area (108) comprising boundaries confining the work area (108), wherein for critical ones of the grid points (112) lying within a predefined boundary zone bordering the boundaries and for which no quality with which the vehicle can be navigated is available or for which the quality with which the vehicle can be navigated does not fulfill the second minimum quality criterion, the scheduling further comprises sending a signal to a user in case the movement trajectory (410) of the vehicle (100) is within a predefined distance from the critical ones of the grid points.

27. The robotic vehicle of clause 26, the signal indicating the one or more points in time when the movement trajectory (410) of the vehicle (100) is within the predefined distance from the critical grid points.

28. The robotic vehicle of clause 26 or 27, wherein execution of the instructions (124) by the processor further causes the vehicle (100) for receiving remote-

control signals from the user in response to the sending of the signal to the user, the remote-control signals causing the vehicle (100) for performing

- a movement of the vehicle (100) to one or more of the critical grid points (112),
- repeating the steps of the quality determination process during the movement for the grid points (112) traveled during the movement and with the first point in time being the actual point in time of movement on the respective grid point (112).

29. A method for operating a robotic vehicle (100) for movable operation in a work area (108), the movable operation comprising a soil cultivation, the work area (108) being represented by a set of discretized coordinate grid points (112), the vehicle (100) comprising a position detector, the method comprising performing a quality determination process comprising for a given grid point and a first point in time determining a quality with which the vehicle can be navigated at the given grid point using the position detector, wherein the method further comprises

- performing an initialization process, the initialization process comprising repeatedly performing the quality determination process at different first points in time and different given grid points selected from a subset of the grid points (112),
- aborting the initialization process in case the number of grid points for which the quality with which the vehicle can be navigated at the given grid point was determined exceeds a predefined initialization threshold.

30. A computer program product comprising computer executable instructions (124) to perform the method of clause 29.

Claims

1. A robotic vehicle (100) for movable operation in a work area (108), the movable operation comprising a soil cultivation, the work area (108) being represented by a set of discretized coordinate grid points (112), the vehicle (100) comprising a position detector and a controller (118), the controller (118) comprising a memory (122) and a processor, the memory (122) comprising instructions (124), wherein execution of the instructions (124) by the processor causes the vehicle (100) for performing a quality determination process comprising for a given grid point and a first point in time determining a quality with which the vehicle can be navigated at the given grid point using the position detector, wherein execution of the instructions (124) by the processor further causes the vehicle (100) to

- perform an initialization process, the initialization process comprising repeatedly performing the quality determination process at different first points in time and different given grid points selected from a subset of the grid points (112),
- abort the initialization process in case the number of grid points for which the quality with which the vehicle can be navigated at the given grid point was determined exceeds a predefined initialization threshold.

2. The robotic vehicle (100) of claim 1, the position detector comprising a Global Navigation Satellite System, GNSS, receiver (106), the quality determination process comprising an accuracy determination process comprising for a given grid point and a first point in time:
 - receiving a first set of GNSS signals (114) from a vehicle base (104), the first set of GNSS signals (114) having been acquired by the vehicle base at the first point in time, the vehicle base (104) being spaced apart from the vehicle (100),
 - receiving at the first point in time a second set of GNSS signals (116) from the GNSS receiver (106), the determining of the quality with which the vehicle can be navigated at the given grid comprising a determining an accuracy of a location determination, the location determination being based on the second set of GNSS signals (116), the determination of the accuracy being based on a comparison of the signal qualities of the first set of GNSS signals (114) and the second set of GNSS signals (116).
3. The robotic vehicle (100) of claim 1 or 2, the predefined initialization threshold being a minimum share of grid points relative to all grid points of the set of discretized coordinate grid points (112).
4. The robotic vehicle (100) of any of the previous claims, wherein execution of the instructions (124) by the processor further causes the vehicle (100) for planning the movable operation based on at least some of the grid points (112) for which a quality with which the vehicle can be navigated is available and the quality with which the vehicle can be navigated.
5. The robotic vehicle (100) of any of the previous claims, wherein the first and second GNSS signals are received from satellites (200) that are located at certain satellite positions (208) in the sky above the base (104) and the vehicle (100), the comparison of the signal qualities of the first set of GNSS signals (114) and the second set of GNSS signals (116) resulting in a quality number per satellite position (208).
6. The robotic vehicle (100) of any of the previous claims, wherein execution of the instructions (124) by the processor causes the vehicle (100) further for performing a predicting process for at least some of the grid points (112), the predicting process forecasting the quality with which the vehicle can be navigated for points in time future to the respective first point in time.
7. The robotic vehicle (100) of claim 6, the predicting process forecasting the accuracy of the location determination for at least some of the grid points (112) of the subset using at least one of GNSS Ephemerides, Almanacs and satellite repeat cycles applied on the first (114) or second set of GNSS signals (116) received at the respective first point in time.
8. The robotic vehicle (100) of claim 6, the predicting process forecasting the accuracy of the location determination comprising: forecasting a reception of first or second GNSS signals for said points in time future to the first point in time from satellites (200) located at a sky area around the certain satellite positions (208), the accuracy of the location determination being forecasted using the forecasted reception of the first or second GNSS signals.
9. The robotic vehicle (100) of claim 8, wherein per satellite position (208) the forecasting of the accuracy of the location determination is performed using
 - the forecasted reception of the first GNSS signals weighted by the quality number of that satellite position (208) or
 - the forecasted reception of the second GNSS signals excluding GNSS signals from satellite positions (208) for which the quality number does not fulfill a first minimum quality criterion.
10. The robotic vehicle (100) of claims 8 or 9, the sky above the base (104) and the vehicle (100) being represented by a set of discretized zones (206), the sky area around a certain satellite position (208) being confined by the boundaries which confine the zone (206) in which the satellite position (208) is located.
11. The robotic vehicle (100) of claim 8, the predicting process further comprising determining a sky area of good reception (302) which comprises at least some of the certain satellite positions (208) for which the quality number of that satellite position fulfills a first minimum quality criterion, the sky area around a certain satellite position being confined by the boundaries which confine the sky area of good reception (302).
12. The robotic vehicle (100) of any of the previous claims 5-11, wherein the determination of the accuracy of the location determination is only considering GNSS signals from satellite positions (208) for which the quality number of that satellite positions (208) fulfills a first minimum quality criterion.
13. The robotic vehicle (100) of claim 12, wherein in case with respect to a given grid point the quality number for a certain satellite position (208) does not fulfill a first minimum quality criterion, for that grid point any GNSS signals from said satellite position (208) are

excluded for the planning of the movable operation.

14. The robotic vehicle (100) of any of the previous claims, the abortion of the initialization process being performed in case the number of grid points for which the quality with which the vehicle can be navigated was determined to fulfill a second minimum quality criterion exceeds the predefined initialization threshold.

15. A method for operating a robotic vehicle (100) for movable operation in a work area (108), the movable operation comprising a soil cultivation, the work area (108) being represented by a set of discretized coordinate grid points (112), the vehicle (100) comprising a position detector, the method comprising performing a quality determination process comprising for a given grid point and a first point in time determining a quality with which the vehicle can be navigated at the given grid point using the position detector, wherein the method further comprises

- performing an initialization process, the initialization process comprising repeatedly performing the quality determination process at different first points in time and different given grid points selected from a subset of the grid points (112),
- aborting the initialization process in case the number of grid points for which the quality with which the vehicle can be navigated at the given grid point was determined exceeds a predefined initialization threshold.

16. A computer program product comprising computer executable instructions (124) to perform the method of claim 15.

Amended claims in accordance with Rule 137(2) EPC.

1. A robotic vehicle (100) for movable operation in a work area (108), the movable operation comprising a soil cultivation, the work area (108) being represented by a set of discretized coordinate grid points (112), the vehicle (100) comprising a position detector and a controller (118), the controller (118) comprising a memory (122) and a processor, the memory (122) comprising instructions (124), wherein execution of the instructions (124) by the processor causes the vehicle (100) for performing a quality determination process comprising for a given grid point and a first point in time determining a quality with which the vehicle can be navigated at the given grid point using the position detector, wherein execution of the instructions (124) by the processor further causes the vehicle (100) to

- perform an initialization process for acquiring information necessary to start the movable operation, the initialization process comprising repeatedly performing the quality determination process at different first points in time and different given grid points selected from a subset of the grid points (112),
- abort the initialization process in case the number of grid points for which the quality with which the vehicle can be navigated at the given grid point was determined exceeds a predefined initialization threshold,

wherein execution of the instructions (124) by the processor further causes the vehicle (100) for planning the movable operation based on at least some of the grid points (112) for which a quality with which the vehicle can be navigated is available and the quality with which the vehicle can be navigated, wherein execution of the instructions (124) by the processor further causes the vehicle (100) to start the movable operation in the work area.

2. The robotic vehicle (100) of claim 1, the position detector comprising a Global Navigation Satellite System, GNSS, receiver (106), the quality determination process comprising an accuracy determination process comprising for a given grid point and a first point in time:

- receiving a first set of GNSS signals (114) from a vehicle base (104), the first set of GNSS signals (114) having been acquired by the vehicle base at the first point in time, the vehicle base (104) being spaced apart from the vehicle (100),
- receiving at the first point in time a second set of GNSS signals (116) from the GNSS receiver (106), the determining of the quality with which the vehicle can be navigated at the given grid comprising a determining an accuracy of a location determination, the location determination being based on the second set of GNSS signals (116), the determination of the accuracy being based on a comparison of the signal qualities of the first set of GNSS signals (114) and the second set of GNSS signals (116).

3. The robotic vehicle (100) of claim 1 or 2, the predefined initialization threshold being a minimum share of grid points relative to all grid points of the set of discretized coordinate grid points (112).

4. The robotic vehicle (100) of any of claims 2 to 3, wherein the first and second GNSS signals are received from satellites (200) that are located at certain satellite positions (208) in the sky above the base (104) and the vehicle (100), the comparison of the signal qualities of the first set of GNSS signals (114)

and the second set of GNSS signals (116) resulting in a quality number per satellite position (208).

5. The robotic vehicle (100) of any of claims 2 to 4, wherein execution of the instructions (124) by the processor causes the vehicle (100) further for performing a predicting process for at least some of the grid points (112), the predicting process forecasting the quality with which the vehicle can be navigated for points in time future to the respective first point in time. 5 10
6. The robotic vehicle (100) of claim 5, the predicting process forecasting the accuracy of the location determination for at least some of the grid points (112) of the subset using at least one of GNSS Ephemerides, Almanacs and satellite repeat cycles applied on the first (114) or second set of GNSS signals (116) received at the respective first point in time. 15 20
7. The robotic vehicle (100) of claim 5, the predicting process forecasting the accuracy of the location determination comprising: forecasting a reception of first or second GNSS signals for said points in time future to the first point in time from satellites (200) located at a sky area around the certain satellite positions (208), the accuracy of the location determination being forecasted using the forecasted reception of the first or second GNSS signals. 25 30
8. The robotic vehicle (100) of claim 7, wherein per satellite position (208) the forecasting of the accuracy of the location determination is performed using 35
 - the forecasted reception of the first GNSS signals weighted by the quality number of that satellite position (208) or
 - the forecasted reception of the second GNSS signals excluding GNSS signals from satellite positions (208) for which the quality number does not fulfill a first minimum quality criterion. 40
9. The robotic vehicle (100) of claims 7 or 8, the sky above the base (104) and the vehicle (100) being represented by a set of discretized zones (206), the sky area around a certain satellite position (208) being confined by the boundaries which confine the zone (206) in which the satellite position (208) is located. 45 50
10. The robotic vehicle (100) of claim 7, the predicting process further comprising determining a sky area of good reception (302) which comprises at least some of the certain satellite positions (208) for which the quality number of that satellite position fulfills a first minimum quality criterion, the sky area around a certain satellite position being confined by the 55

boundaries which confine the sky area of good reception (302).

11. The robotic vehicle (100) of any of the previous claims 4-10, wherein the determination of the accuracy of the location determination is only considering GNSS signals from satellite positions (208) for which the quality number of that satellite positions (208) fulfills a first minimum quality criterion.
12. The robotic vehicle (100) of claim 11, wherein in case with respect to a given grid point the quality number for a certain satellite position (208) does not fulfill a first minimum quality criterion, for that grid point any GNSS signals from said satellite position (208) are excluded for the planning of the movable operation.
13. The robotic vehicle (100) of any of the previous claims, the abortion of the initialization process being performed in case the number of grid points for which the quality with which the vehicle can be navigated was determined to fulfill a second minimum quality criterion exceeds the predefined initialization threshold.
14. A method for operating a robotic vehicle (100) for movable operation in a work area (108), the movable operation comprising a soil cultivation, the work area (108) being represented by a set of discretized coordinate grid points (112), the vehicle (100) comprising a position detector, the method comprising performing a quality determination process comprising for a given grid point and a first point in time determining a quality with which the vehicle can be navigated at the given grid point using the position detector, wherein the method further comprises
 - performing an initialization process for acquiring information necessary to start the movable operation, the initialization process comprising repeatedly performing the quality determination process at different first points in time and different given grid points selected from a subset of the grid points (112),
 - aborting the initialization process in case the number of grid points for which the quality with which the vehicle can be navigated at the given grid point was determined exceeds a predefined initialization threshold,

wherein execution of the instructions (124) by the processor further causes the vehicle (100) for planning the movable operation based on at least some of the grid points (112) for which a quality with which the vehicle can be navigated is available and the quality with which the vehicle can be navigated, wherein execution of the instructions (124) by the processor further causes the vehicle (100) to start

the movable operation in the work area..

15. A computer program product comprising computer executable instructions (124) to perform the method of claim 14.

DOCUMENTS CONSIDERED TO BE RELEVANT			
Category	Citation of document with indication, where appropriate, of relevant passages	Relevant to claim	CLASSIFICATION OF THE APPLICATION (IPC)
X	US 9 573 275 B2 (HUSQVARNA AB [SE]) 21 February 2017 (2017-02-21)	1,3, 14-16	INV. G01S19/28
Y	* column 5, line 17 - column 7, line 15; figures 1-4 *	2,4-13	G01S19/07 G01S19/43 G01S19/41 G01S19/49
Y	----- WO 2006/132003 A1 (UNIV TOKYO NAT UNIV CORP [JP]; KUBO NOBUAKI [JP] ET AL.) 14 December 2006 (2006-12-14) * paragraph [0162] - paragraph [0280]; figure 9 *	2,5-13	
Y	----- US 2018/253096 A1 (HOLGERSSON JONAS [SE] ET AL) 6 September 2018 (2018-09-06) * paragraph [0042] - paragraph [0061]; figures 1-6 *	4	
A	----- AUAT CHEEIN FERNANDO ALFREDO ET AL: "Agricultural Robotics: Unmanned Robotic Service Units in Agricultural Tasks", IEEE INDUSTRIAL ELECTRONICS MAGAZINE, IEEE, US, vol. 7, no. 3, 1 September 2013 (2013-09-01), pages 48-58, XP011527058, ISSN: 1932-4529, DOI: 10.1109/MIE.2013.2252957 [retrieved on 2013-09-18] * the whole document *	1-16	TECHNICAL FIELDS SEARCHED (IPC) G01S
The present search report has been drawn up for all claims			
Place of search Munich		Date of completion of the search 7 August 2019	Examiner Fanjul Caudevilla, J
CATEGORY OF CITED DOCUMENTS X : particularly relevant if taken alone Y : particularly relevant if combined with another document of the same category A : technological background O : non-written disclosure P : intermediate document		T : theory or principle underlying the invention E : earlier patent document, but published on, or after the filing date D : document cited in the application L : document cited for other reasons & : member of the same patent family, corresponding document	

EPO FORM 1503 03.02 (P04C01)

**ANNEX TO THE EUROPEAN SEARCH REPORT
ON EUROPEAN PATENT APPLICATION NO.**

EP 19 15 7239

5

This annex lists the patent family members relating to the patent documents cited in the above-mentioned European search report.
The members are as contained in the European Patent Office EDP file on
The European Patent Office is in no way liable for these particulars which are merely given for the purpose of information.
